

# Chapter 16: Security

# Chapter 16: Security

---

- The Security Problem ✓
- Program Threats ✓
- System and Network Threats ✓
- Cryptography as a Security Tool
- User Authentication
- Implementing Security Defenses
- Firewalling to Protect Systems and Networks
- Computer-Security Classifications
- An Example: Windows 7

Antivirus , firewall

# Objectives

---

- Discuss security threats and attacks
- Explain the fundamentals of encryption, authentication, and hashing
- Examine the uses of cryptography in computing
- Describe the various countermeasures to security attacks

# The Security Problem

- System **secure** if resources used and accessed as intended under all circumstances
  - Unachievable
- ✓ ■ **Intruders (crackers)** attempt to breach security
- ✓ ■ **Threat** is potential security violation *(Before attack)*
- ✓ ■ **Attack** is attempt to breach security
- Attack can be accidental or malicious
- Easier to protect against accidental than malicious misuse

# Security Violation Categories

- ✓ ■ Breach of confidentiality
  - Unauthorized reading of data
- ✓ ■ Breach of integrity
  - Unauthorized modification of data
- ✓ ■ Breach of availability
  - Unauthorized destruction of data
- ✓ ■ Theft of service
  - Unauthorized use of resources
- ✓ ■ Denial of service (DOS)
  - Prevention of legitimate use

HTTP FTP etc.

# Security Violation Methods

## Masquerading (breach authentication)

- Pretending to be an authorized user to escalate privileges (permission)

## Replay attack

- As is or with message modification

## Man-in-the-middle attack

- Intruder sits in data flow, masquerading as sender to receiver and vice versa

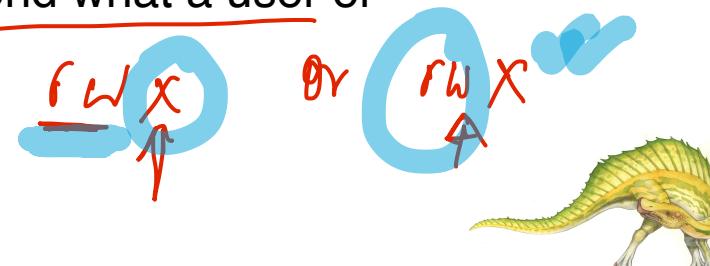

## Session hijacking

- Intercept an already-established session to bypass authentication

## Privilege escalation

- Common attack type with access beyond what a user or resource is supposed to have

# Security Measure Levels

- Impossible to have absolute security, but make cost to perpetrator sufficiently high to deter most intruders
- Security must occur at four levels to be effective:

- **Physical**

- ▶ Data centers, servers, connected terminals

- **Application**

- ▶ Benign or malicious apps can cause security problems

- **Operating System**

- ▶ Protection mechanisms, debugging

(Bug Fix)

- **Network**

- ▶ Intercepted communications, interruption, DOS

(Denial of Service)

- Security is as weak as the weakest link in the chain

- Humans a risk too via **phishing** and **social-engineering** attacks

- But can too much security be a problem?

# Program Threats

- Many variations, many names

## Trojan Horse

- Code segment that misuses its environment
- Exploits mechanisms for allowing programs written by users to be executed by other users
- **Spyware, pop-up browser windows, covert channels**
- Up to 80% of spam delivered by spyware-infected systems

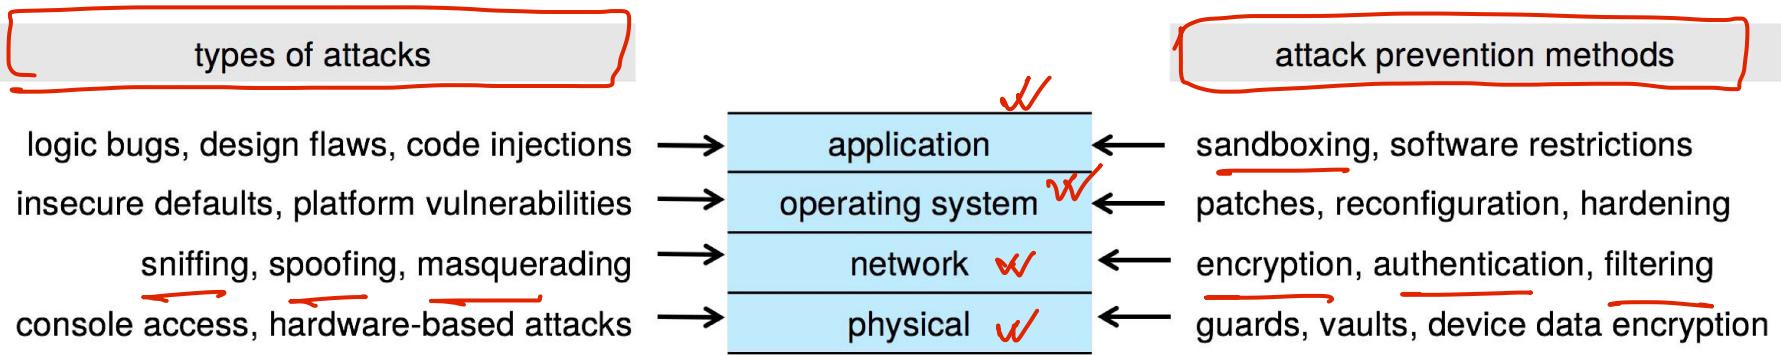

## Trap Door

- Specific user identifier or password that circumvents normal security procedures
- Could be included in a compiler
- How to detect them?

# Four-layered Model of Security

When data is transmitted across networks, if the data packets are not encrypted, the data within the network packet can be read using a sniffer.

important

A spoofing attack is a situation in which a person or program successfully identifies as another by falsifying data, to gain an illegitimate advantage.

# Program Threats (Cont.)

- ✓ ■ **Malware** - Software designed to exploit, disable, or damage computer
- ✓ ■ **Trojan Horse** – Program that acts in a clandestine manner
  - **Spyware** – Program frequently installed with legitimate software to display adds, capture user data
  - **Ransomware** – locks up data via encryption, demanding payment to unlock it
- ✓ ■ Others include trap doors, logic bombs
- ✓ ■ All try to violate the Principle of Least Privilege

## THE PRINCIPLE OF LEAST PRIVILEGE

“The principle of least privilege. Every program and every privileged user of the system should operate using the least amount of privilege necessary to complete the job. The purpose of this principle is to reduce the number of potential interactions among privileged programs to the minimum necessary to operate correctly, so that one may develop confidence that unintentional, unwanted, or improper uses of privilege do not occur.”—Jerome H. Saltzer, describing a design principle of the Multics operating system in 1974: <https://pdfs.semanticscholar.org/1c8d/06510ad449ad24fbdd164f8008cc730cab47.pdf>.

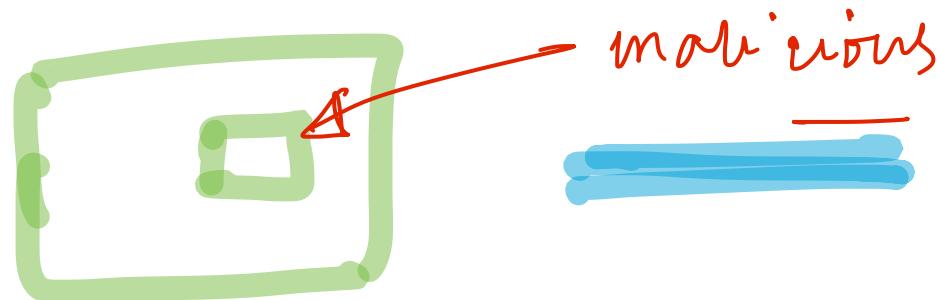

- ✓ ■ Goal frequently is to leave behind Remote Access Tool (RAT) for repeated access

# Code Injection

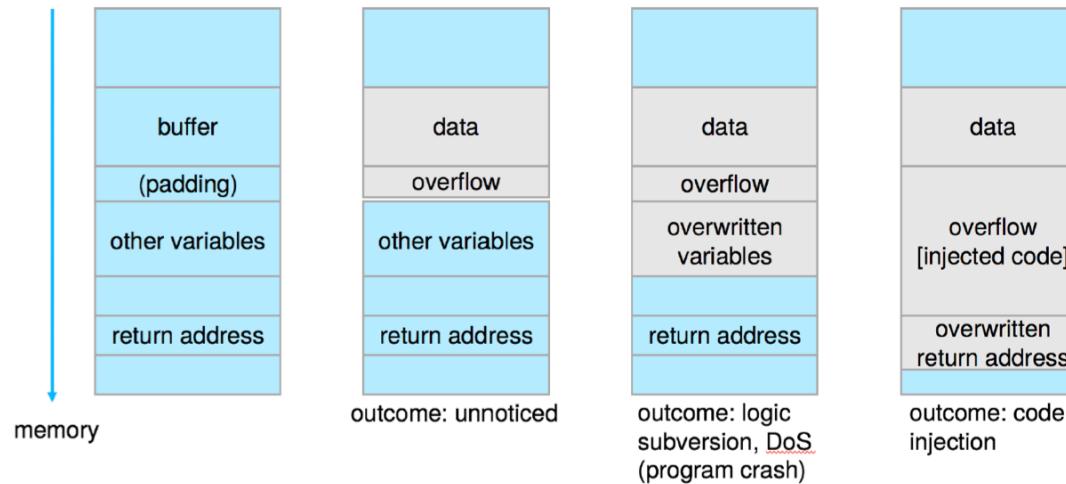

- **Code-injection attack** occurs when system code is not malicious but has bugs allowing executable code to be added or modified
  - Results from poor or insecure programming paradigms, commonly in low level languages like C or C++ which allow for direct memory access through pointers
  - Goal is a buffer overflow in which code is placed in a buffer and execution caused by the attack
  - Can be run by script kiddies – use tools written but exploit identifiers

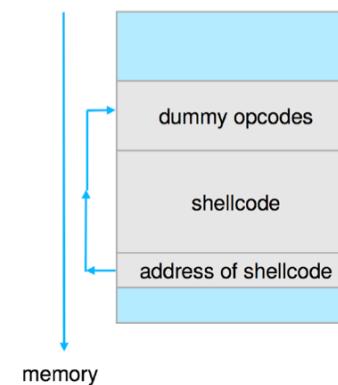

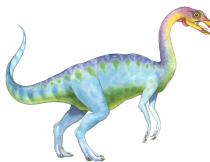

# Code Injection (cont.)

- Outcomes from code injection include:

- Frequently use trampoline to code execution to exploit buffer overflow:

# Great Programming Required?

- For the first step of determining the bug, and second step of writing exploit code, yes
- **Script kiddies** can run pre-written exploit code to attack a given system
- Attack code can get a shell with the processes' owner's permissions
  - Or open a network port, delete files, download a program, etc
- Depending on bug, attack can be executed across a network using allowed connections, bypassing firewalls
- Buffer overflow can be disabled by disabling stack execution or adding bit to page table to indicate “non-executable” state
  - Available in SPARC and x86
  - But still have security exploits

# Program Threats (Cont.)

## Viruses

- Code fragment embedded in legitimate program
- Self-replicating, designed to infect other computers
- Very specific to CPU architecture, operating system, applications
- Usually borne via email or as a macro
- Visual Basic Macro to reformat hard drive

```
Sub AutoOpen ()  
    Dim oFS  
    Set oFS = CreateObject("Scripting.FileSystemObject")  
    vs = Shell("c:command.com /k format c:",vbHide)  
End Sub
```

# Program Threats (Cont.)

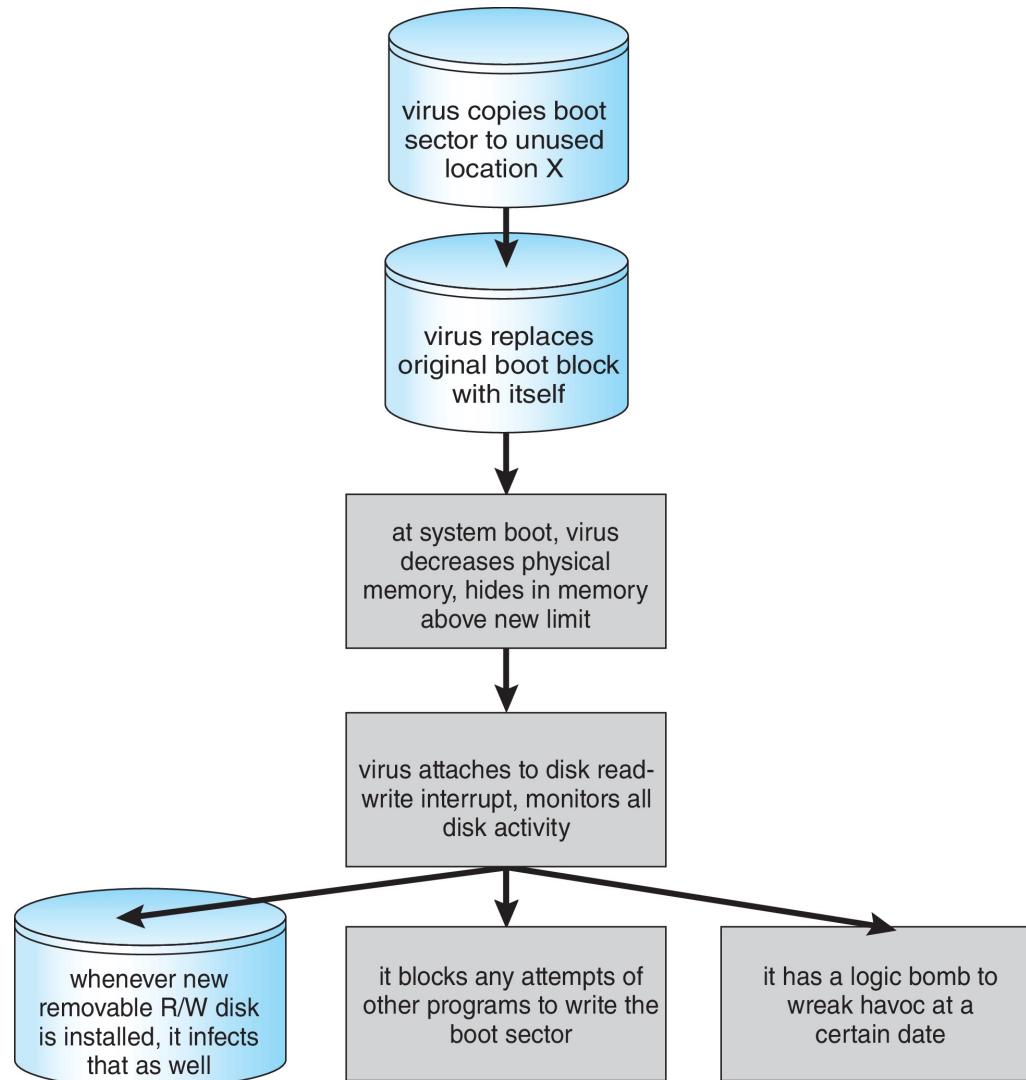

- **Virus dropper** inserts virus onto the system
- Many categories of viruses, literally many thousands of viruses
  - File / parasitic
  - Boot / memory
  - Macro
  - Source code
  - Polymorphic to avoid having a **virus signature**
  - Encrypted
  - Stealth
  - Tunneling
  - Multipartite
  - Armored

# A Boot-sector Computer Virus

# The Threat Continues

- Attacks still common, still occurring
- Attacks moved over time from science experiments to tools of organized crime
  - Targeting specific companies
  - Creating botnets to use as tool for spam and DDOS delivery
  - **Keystroke logger** to grab passwords, credit card numbers
- Why is Windows the target for most attacks?
  - Most common
  - Everyone is an administrator
    - ▶ Licensing required?
  - **Monoculture** considered harmful

56/57 Keystroke logger

# System and Network Threats

- Some systems “open” rather than **secure by default**
  - Reduce **attack surface**
  - But harder to use, more knowledge needed to administer
- Network threats harder to detect, prevent
  - Protection systems weaker
  - More difficult to have a shared secret on which to base access
  - No physical limits once system attached to internet
    - ▶ Or on network with system attached to internet
  - Even determining location of connecting system difficult
    - ▶ IP address is only knowledge

# System and Network Threats (Cont.)

■ **Worms** – use **spawn** mechanism; standalone program

■ Internet worm

- Exploited UNIX networking features (remote access) and bugs in *finger* and *sendmail* programs
- Exploited trust-relationship mechanism used by *rsh* to access friendly systems without use of password
- **Grappling hook** program uploaded main worm program
  - ▶ 99 lines of C code
- Hooked system then uploaded main code, tried to attack connected systems
- Also tried to break into other users accounts on local system via password guessing
- If target system already infected, abort, except for every 7<sup>th</sup> time

# System and Network Threats (Cont.)

## ■ Port scanning

- Automated attempt to connect to a range of ports on one or a range of IP addresses
- Detection of answering service protocol
- Detection of OS and version running on system
- nmap scans all ports in a given IP range for a response
- nessus has a database of protocols and bugs (and exploits) to apply against a system
- Frequently launched from **zombie systems**
  - ▶ To decrease trace-ability

# System and Network Threats (Cont.)

## Denial of Service

- Overload the targeted computer preventing it from doing any useful work
- **Distributed Denial-of-Service (DDoS)** come from multiple sites at once
- Consider the start of the IP-connection handshake (SYN)
  - ▶ How many started-connections can the OS handle?
- Consider traffic to a web site
  - ▶ How can you tell the difference between being a target and being really popular?
- Accidental – CS students writing bad `fork()` code
- Purposeful – extortion, punishment

## Port scanning

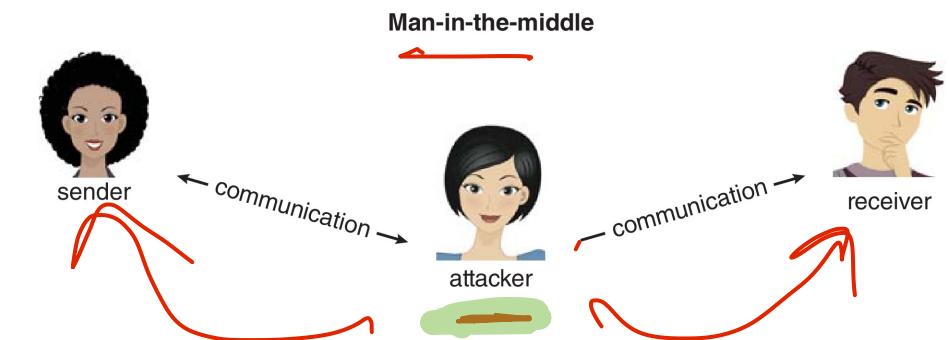

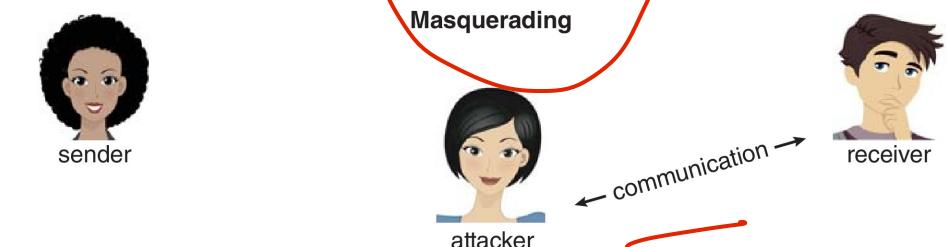

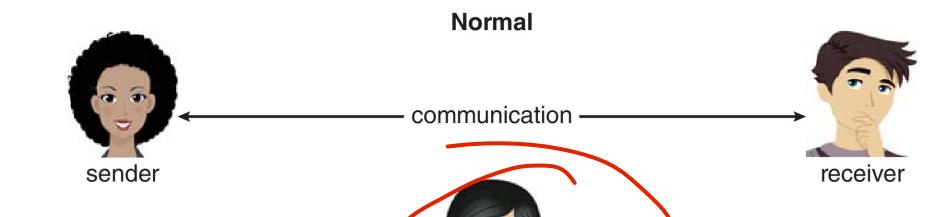

- Automated tool to look for network ports accepting connections
- Used for good and evil

# Standard Security Attacks

Examples ↗

# Cryptography

- Means to constrain potential senders (*sources*) and / or receivers (*destinations*) of *messages*
  - Based on secrets (**keys**)
  - Enables
    - ▶ Confirmation of source
    - ▶ Receipt only by certain destination
    - ▶ Trust relationship between sender and receiver

# Encryption

*Encryption is a way of scrambling data so that only authorized parties can understand the information. In technical terms, it is the process of converting human-readable plaintext to incomprehensible text, also known as ciphertext.*

# ✓ Encryption

- Constrains the set of possible receivers of a message
- **Encryption** algorithm consists of
  - Set  $K$  of keys
  - Set  $M$  of Messages
  - Set  $C$  of ciphertexts (encrypted messages)
  - A function  $E : K \rightarrow (M \rightarrow C)$ . That is, for each  $k \in K$ ,  $E_k$  is a function for generating ciphertexts from messages
    - ▶ Both  $E$  and  $E_k$  for any  $k$  should be efficiently computable functions
  - A function  $D : K \rightarrow (C \rightarrow M)$ . That is, for each  $k \in K$ ,  $D_k$  is a function for generating messages from ciphertexts
    - ▶ Both  $D$  and  $D_k$  for any  $k$  should be efficiently computable functions

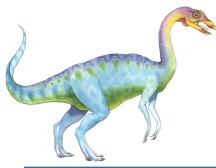

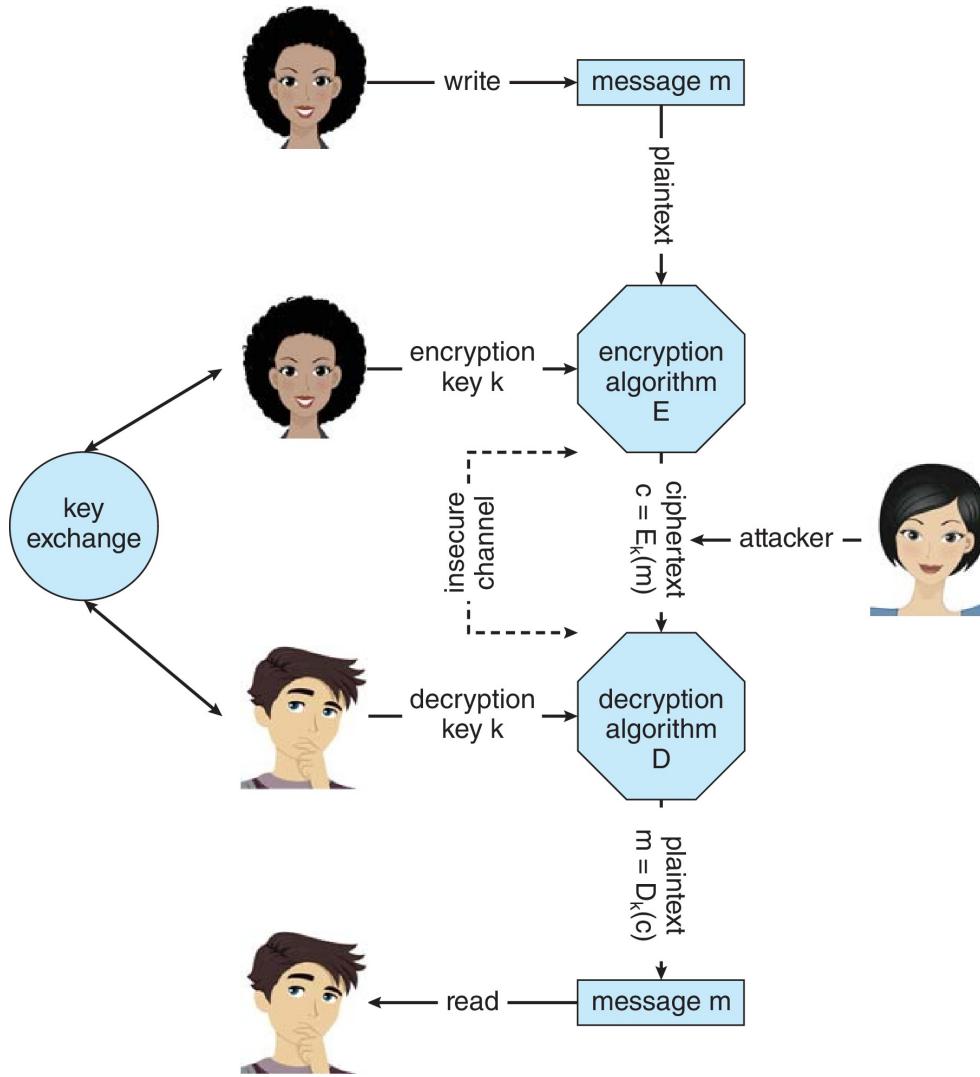

# Encryption (Cont.)

- An encryption algorithm must provide this essential property:  
Given a ciphertext  $c \in C$ , a computer can compute  $m$  such  
that  $E_k(m) = c$  only if it possesses  $k$ 
  - Thus, a computer holding  $k$  can decrypt ciphertexts to  
the plaintexts used to produce them, but a computer not  
holding  $k$  cannot decrypt ciphertexts
  - Since ciphertexts are generally exposed (for example,  
sent on the network), it is important that it be infeasible  
to derive  $k$  from the ciphertexts

# Secure Communication over Insecure Medium

# Asymmetric Encryption

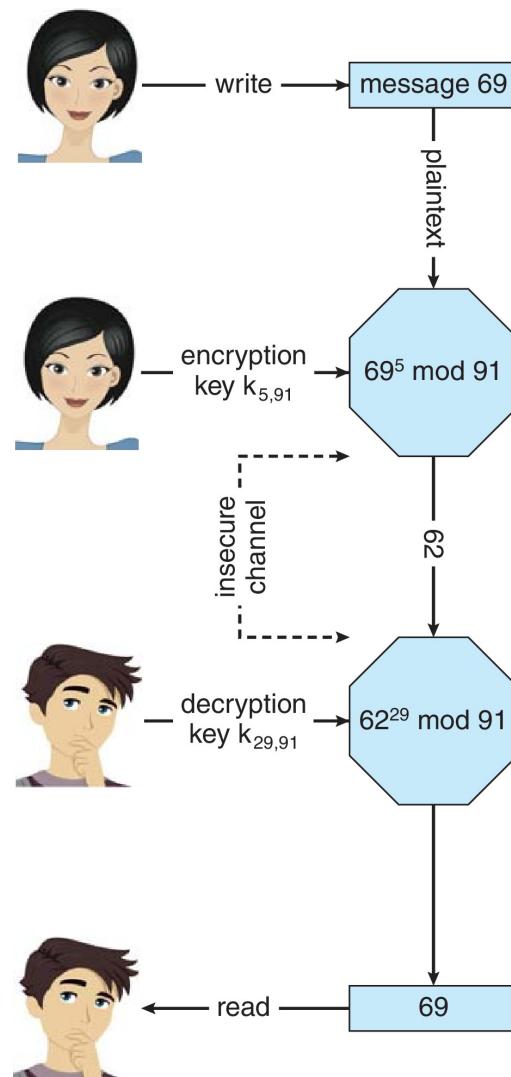

---

- **Public-key encryption** based on each user having two keys:
  - **public key** – published key used to encrypt data
  - **private key** – key known only to individual user used to decrypt data
- Must be an encryption scheme that can be made public without making it easy to figure out the decryption scheme
  - Most common is **RSA** block cipher
  - Efficient algorithm for testing whether or not a number is prime
  - No efficient algorithm is known for finding the prime factors of a number

# Encryption using RSA Asymmetric Cryptography

# Digital Certificates

---

- Proof of who or what owns a public key
- Public key digitally signed a trusted party
- Trusted party receives proof of identification from entity and certifies that public key belongs to entity
- **Certificate authority** are trusted party – their public keys included with web browser distributions
  - They vouch for other authorities via digitally signing their keys, and so on

# Encryption Example - TLS

- Insertion of cryptography at one layer of the ISO network model (the transport layer)
- SSL – Secure Socket Layer (also called TLS) 
- Cryptographic protocol that limits two computers to only exchange messages with each other
  - Very complicated, with many variations
- Used between web servers and browsers for secure communication (credit card numbers)
- The server is verified with a **certificate** assuring client is talking to correct server
- Asymmetric cryptography used to establish a secure **session key** (symmetric encryption) for bulk of communication during session
- Communication between each computer then uses symmetric key cryptography
- More details in textbook

# User Authentication

---

- Crucial to identify user correctly, as protection systems depend on user ID
- User identity most often established through **passwords**, can be considered a special case of either keys or capabilities
- Passwords must be kept secret
  - Frequent change of passwords
  - History to avoid repeats
  - Use of “non-guessable” passwords
  - Log all invalid access attempts (but not the passwords themselves)
  - Unauthorized transfer
- Passwords may also either be encrypted or allowed to be used only once
  - Does encrypting passwords solve the exposure problem?
    - ▶ Might solve **sniffing**
    - ▶ Consider **shoulder surfing**
    - ▶ Consider Trojan horse keystroke logger
    - ▶ How are passwords stored at authenticating site?

# Passwords

- Encrypt to avoid having to keep secret
  - But keep secret anyway (i.e. Unix uses superuser-only readable file /etc/shadow)
  - Use algorithm easy to compute but difficult to invert
  - Only encrypted password stored, never decrypted
  - Add “salt” to avoid the same password being encrypted to the same value
- One-time passwords
  - Use a function based on a seed to compute a password, both user and computer
  - Hardware device / calculator / key fob to generate the password
    - ▶ Changes very frequently
- Biometrics
  - Some physical attribute (fingerprint, hand scan)
- Multi-factor authentication
  - Need two or more factors for authentication
    - ▶ i.e. USB “dongle”, biometric measure, and password

# End of Chapter 16
